The vibrational relaxation processes in  $\text{BeAl}_2\text{O}_4:\text{Cr}^{3+}$  were studied by analysing the rise time of luminescence which was found to be 100 ps when excited by 532 nm.

## INTRODUCTION

Chromium-doped  $\text{BeAl}_2\text{O}_4$  is a kind of new laser materials in which laser action occurs not only on sharp R-lines but also in the vibronic side-band where the lasing is broadly tunable<sup>1,2</sup>, so the electron-LO phonon interaction is important in this material, we try to study the dynamic processes of electron-LO phonon interaction. In  $\text{BeAl}_2\text{O}_4:\text{Cr}^{3+}$  the transition-metal ion  $\text{Cr}^{3+}$  substitutes  $\text{Al}^{3+}$  into two inequivalent crystal sites 75% in mirror sites(Cs) and the rest in inversion sites(Ci). According to selection rule, the R-lines in Cs site(Rs) are electric-dipole transition and the R-lines in Ci site(Ri) are magnetic-dipole transition<sup>2</sup>, so the Rs-lines are especially strong in the luminescence spectrum, we pay attention to study their luminescence dynamic properties.

## EXPERIMENT

We excited the sample  $\text{BeAl}_2\text{O}_4:\text{Cr}^{3+}$  by means of an active-mode-locked YAG laser (pulse width 100 ps, second harmonic wave length 532nm), and then used a set of interference filters and a high speed streak camera to study the luminescence dynamic process of Rs-lines. As the luminescence life times of Rs-lines are very long (ms), the streak camera should use the gate mode function to sample a special period of the luminescence process.

## THEORY

When the luminescence centers are excited by

laser pulse 532 nm, the electrons come into high excited states<sup>2</sup>. Then two processes will take place (1) hot luminescence, the luminescence of electron in high excited states; (2) vibrational relaxation, the electron in higher excited states relaxes down to lower excited states with emission of LO phonons. As the vibrational relaxation is very quick (pico-second process), the highly excited electrons relax down to lower excited states, the hot luminescence is very weak compared with the electron-LO phonon interaction. After relaxed down to the lowest excited states  $^2\text{E}$ , luminescence Rs-lines appears. The dynamic process can be expressed as follow

$$\begin{cases} dN_1/dt = -Tn^{-1}N_1 \\ dN_2/dt = Tn^{-1}N_1 - Te^{-1}N_2 \end{cases}$$

where  $N_1$  is the electron population in higher excited states( $4T_2$ ),  $N_2$  is that in the lowest excited states( $^2\text{E}$ ).  $Te$  is the life time of energy level  $^2\text{E}$ ,  $Tn$  is the interaction time of electron-LO phonon. By solving the equations we have

$$N_1 = N_0[1-\exp(-t/T)], Tn \ll Te$$

where  $1/T = 1/Tn - 1/Te$ . The luminescence of Rs-lines is given as

$$I = Te^{-1} N_0[1-\exp(-t/T)]$$

By studying the time developing process of Rs-lines, we can get some information about the time scale of the electron-LO phonon interaction.

## RESULTS AND DISCUSSION

FIGURE 1  
Luminescence spectrum of  $\text{BeAl}_2\text{O}_4:\text{Cr}^{3+}$  excited by 488 nm.

First we used a Raman Spectrograph to measure the luminescence spectrum of  $\text{BeAl}_2\text{O}_4:\text{Cr}^{3+}$  excited by  $\text{Ar}^+$ -laser 488 nm at room temperature. The result is given in Figure 1.

The vibronic sidebands are electric-dipole-LO phonon transitions of  $\text{Cr}^{3+}$  at Ci site. The LO phonon energy is  $250\text{ cm}^{-1}$ .

Then we studied the time resolved luminescence spectrum of Rs-lines, the result is shown in Figure 2.

As the laser pulse is 100 ps wide, we take a deconvolution method to get the real rising time of Rs-lines. Suppose  $F(t)$  is the laser pulse,  $D(t)$  is the observed luminescence rising,  $G(t)$  is the real rising.

$$D(t) = \int_0^t F(x)G(t-x)dx$$

Intergrate both sides between the time limits 0 and  $t$ , put  $G(t)=k[1-\exp(-t/T)]$  into the equation. Note<sup>4</sup>

$$\begin{aligned} & k \int_0^t \exp(-y/T) \int_0^y F(x) \exp(x/T) dx dy \\ &= kT \int_0^t F(x) dx - kT \int_0^t \exp[-(t-x)/T] F(x) dx \\ &= TD(t) \end{aligned}$$

Then we have

$$Z(t) = -TW(t) + k$$

$$\begin{aligned} \text{where } Z(t) &= \int_0^t D(x) dx / \int_0^t \int_0^y F(x) dx dy \\ W(t) &= D(t) / \int_0^t \int_0^y F(x) dx dy \end{aligned}$$

FIGURE 2  
Time resolved luminescence spectrum of Rs-lines

From the experimental results, we calculated  $Z(t)$ ,  $W(t)$ , and drew a curve of  $W(t)$  versus  $Z(t)$ . The curve must be a straight line with slope  $-T$ . In this way, we get  $T=100$  ps. As we know the high excited electrons have excess energy of  $4050\text{ cm}^{-1}$ , the LO phonon energy is  $250\text{ cm}^{-1}$ , there are about  $4050/250 \approx 16$  vibrational levels between high excited states and  $^2E$  states, so the highly excited electrons relax down along the configurational curve by emitting LO phonons, the total relaxation time before luminescence from the lowest excited states ( $^2E$ ) to the ground state, is about 100ps.

#### ACKNOWLEDGEMENT

We should like to thank Mr. Wei Changjiang and Mr. Yang Fang for their help in our experiments.
