ABSTRACT

Metal sulfides have been widely used as the anode materials of sodium-ion batteries (SIBs) due to their high theoretical capacity. However, their inherent low conductivity and irreversible volume expansion limit their electrochemical performance and application. To solve these problems, the MoS₂@Sb₂S₃ heterostructure composites wrapped by 3D interconnected reduce graphene oxide (rGO) are prepared. The MoS₂@Sb₂S₃ heterostructure accelerates the transfer of ions and electrons, and provides rich active sites, which facilitates electrolyte penetration and improves the interfacial reaction kinetics. Wrap 3D interconnected rGO networks around the porous MoS₂@Sb₂S₃ composites to reduce the volume expansion of composite materials in the process of sodiumization and desodiumization, and ensure the structural stability. The theoretical calculation further supports the experimental results that the MoS₂@Sb₂S₃/rGO heterojunction promotes the redistribution of different charge density and optimizes the adsorption energy of the composite for Na⁺, thus accelerating the electrochemical reaction kinetics. The MoS₂@Sb₂S₃/rGO composite as the anode materials of SIBs can achieve a discharge specific capacity of 591.6 mAh g⁻¹ at the second cycle with current density of 5 A g⁻¹, and 162.1 mAh g⁻¹ after 1100 cycles. High-rate capacities are achieved for SIBs (350.4 mAh g⁻¹ @ 1 A g⁻¹, 260.1 mAh g⁻¹ @ 5 A g⁻¹). This work provides a practical method for preparing anode materials of SIBs with excellent electrochemical performance.

1. Introduction

Lithium-ion batteries (LIBs) have developed rapidly in recent years due to their high specific energy and excellent cycle performance. However, their large-scale application in electric energy storage is limited due to low natural abundance and uneven geographical distribution of Li [1–3]. Green, clean, low-cost, high-capacity rechargeable batteries are still highly desired [4–6]. Due to its abundant natural reserves, modest cost and electrochemical characteristics similar to those of LIBs, sodium-ion batteries (SIBs) could be the perfect substitute for LIBs [7,8]. However, traditional commercial graphite as anode material of SIB shows dissatisfied specific capacity, and it has been widely used as anode material of LIBs and has achieved great success. The major factor is that ionic radius of Na⁺ is much larger than that of Li⁺, and it is difficult to insert the graphite lattice during sodiumization or

desodiumization, resulting in huge volume expansion [9,10]. Therefore, finding anode materials with excellent sodium storage capacity and high structural stability is crucial for commercialization of SIBs.

At present, layered metal sulfide MS_x (M = Mo, Sb, Sn, Bi, etc.) has been widely studied as SIB anode material, mainly due to its high theoretical capacity [11–14]. As a feasible anode material for SIB, the theoretical capacity of Sb₂S₃ is 946 mAh g⁻¹. However, the huge volume expansion and poor ionic conductivity of Sb₂S₃ during charging and discharging lead to low specific capacity, poor cycling stability and low cycle life [15–18]. In order to solve these problems, heterostructure composites composed of two different metal sulfides have been widely studied [19–22]. By chemical vapor deposition technology, Fang *et al.* synthesized Sb₂S₃/SnS₂ heterostructure exhibiting impeccable rate performance in SIBs [23]. Li *et al.* synthesized nitrogen-doped carbon-coated CoS₂/Sb₂S₃ core/shell heterostructure, whose unique carbon-

coated heterostructure brought long cycle life [24]. Heterostructure can improve the interfacial reaction kinetics, accelerate the diffusion of ions and electrons, and thus improve the conductivity and electrochemical performance of electrode materials [25]. Meanwhile, the bimetallic sulfide also provides more redox sites and lower optical binding gap [26,27].

The combination of metal sulfide and carbon matrix is also one of the important strategies to solve the above problems. In general, simple carbon coating could effectively reduce the interface resistance, increase the electrical conductivity and improve the electrochemical performance of materials [28]. However, the large radius of Na^+ may still cause the cracking of carbon layer during desodiumization and sodiumization, thus reducing the electrochemical performance [29]. Recently, 3D interconnected reduced graphene oxide (rGO) network, as the electrode material of SIBs, has received great attention owing to its outstanding mechanical ductility, excellent electronic conductivity and significant specific surface area [30,31]. Zhang *et al.* reported SnSb nanoparticle-anchored N-doped 3D rGO as anode of SIBs, and the first cycle discharge specific capacity reached 1169 mAh g^{-1} at 0.1C [32]. Cao *et al.* fabricated $\text{Sb}_2\text{S}_3/\text{FeS}_2/\text{N-rGO}$ hollow nanorods by a two-step solvothermal method, with a high-capacity retention rate of 85.7 % after 1000 cycles at 5 A g^{-1} [33]. Zhao *et al.* reported a new design of $\text{SnO}_2/\text{SnS}_2$ heterostructured quantum dots anchored on nitrogen-doped graphene ($\text{SnO}_2/\text{SnS}_2/\text{NG}$), used for SIBs anode materials to exhibit superstrong ion diffusion kinetics and excellent sodium storage performance [34]. The 3D interconnected rGO network promotes the electrolyte penetration and ion shuttle process, thereby greatly improving the sodium storage performance [35].

Based on above discussion, bimetallic sulfides coated with 3D interconnected rGO network may be a promising way to achieve high-performance SIBs, but the Sb-based anode material family still needs further exploration. In this work, $\text{MoS}_2/\text{Sb}_2\text{S}_3/\text{rGO}$ composite heterostructures are fabricated by hydrothermal vulcanization method. In the composite, 3D interconnected rGO is used as a support template to enhance conductivity and specific surface area, and cushion the volume expansion during charging and discharging. At the same time, the new design of the three-dimensional interconnected conductive skeleton structure greatly shortens the Na^+ diffusion path and increases the contact area between the electrolyte and the active material. The interface between Sb_2S_3 and MoS_2 induces an internal electric field, which promotes Na^+ pumping into the interface, greatly reduces the activation barrier and improves the kinetics of the entire material conversion reaction. In addition, the different redox potentials of Sb_2S_3 and MoS_2 also alleviate the volume expansion during the sodiumization and desodiumization, and ensure the structural stability of the composite. As a result, the excellent performance of SIBs based on $\text{MoS}_2/\text{Sb}_2\text{S}_3/\text{rGO}$ anode is achieved.

2. Experiment

2.1. Synthesis of $\text{Sb}_2\text{MoO}_6/\text{rGO}$

Graphene oxide (GO) was produced by a modified Hummers method [36]. $\text{Sb}_2\text{MoO}_6/\text{rGO}$ was prepared by one-step hydrothermal method. Typically, 0.62 g ammonium molybdate tetrahydrate was dissolved in 25 ml of GO aqueous solution under stirring. Then, 0.456 g antimony trichloride was dissolved in 10 ml absolute ethanol. Mixing the two solutions thoroughly until it turns to dark green. Finally, the mixed solution was transferred into a 50 ml Teflon-lined reactor and kept at $160 \text{ }^\circ\text{C}$ for 36 h. Powder samples were obtained after washing and freeze-drying.

2.2. Synthesis of $\text{MoS}_2/\text{Sb}_2\text{S}_3/\text{rGO}$

The $\text{MoS}_2/\text{Sb}_2\text{S}_3/\text{rGO}$ heterostructures were fabricated by high temperature vulcanization in N_2 atmosphere. At first, 0.2 g $\text{Sb}_2\text{MoO}_6/$

rGO and 0.6 g of sulfur powder were mixed and put in the center of a tube furnace, which is kept at $500 \text{ }^\circ\text{C}$ for 2 h in N_2 . After cooling, the black $\text{MoS}_2/\text{Sb}_2\text{S}_3/\text{rGO}$ powder sample was acquired. For comparison, $\text{MoS}_2/\text{Sb}_2\text{S}_3$ was also produced using the same technique without the addition of GO.

2.3. Material characterization

The samples were characterized by X-ray diffraction (XRD, D/max-2500 PC X-ray diffractometer), field emission scanning electron microscopy (FESEM, S4800, Hitachi Corporation), transmission electron microscopy (TEM, FEI Talos F200), X-ray photoelectron spectroscopy (XPS, Thermo Scientific, Waltham, MA, USA), and Raman spectrometer (Raman, HR-Evolution). The Brunauer-Emmett-Teller (BET) specific surface area and pore size distribution of the samples were determined by N_2 adsorption/desorption (NOVA 2000, Quanta chrome).

2.4. Electrochemical characterization

In an argon glove box, the $\text{MoS}_2/\text{Sb}_2\text{S}_3/\text{rGO}$ electrode was assembled into a CR2032 coin cell. The working electrode was consisted of $\text{MoS}_2/\text{Sb}_2\text{S}_3/\text{rGO}$ -based active material (70 wt%), conductive carbon black (20 wt%), and sodium carboxymethyl cellulose (CMC, 10 wt%). Use an appropriate amount of deionized water as the stirring solvent, grind for 1 h, and coat the slurry on the copper foil. After the copper foil was dried in a vacuum oven at $60 \text{ }^\circ\text{C}$, it was cut into round pieces with a diameter of 1.2 cm, and the active substance load of each piece was between 1.2 and 1.5 mg cm^{-2} . The positive electrode is metal sodium sheet, and the separator is glass fiber membrane (Whatman, GF/D). 1 M NaClO_4 was added to ethylene carbonate/diethyl carbonate (1:1, V/V) as the electrolyte. The galvanostatic charge-discharge (GCD) performance in the voltage range of 0.01–3 V was tested by the blue electricity test system (LAND CT2001A). Cyclic voltammetry (CV) curves were measured in the 0–3 V voltage range at a scan rate of 0.1 mV s^{-1} . Electrochemical impedance spectroscopy (EIS) spectra were recorded at the frequency range of 0.01 Hz to 100 KHz. Both of CV and EIS were test on CHI660E electrochemical workstation (Shanghai Chenhua Instrument Co., Ltd.).

2.5. Computational method

The Materials Studio was employed in the DFT calculation. The Perdew-Wang (PWC) version of the local density approximation (LDA) was applied for the exchange and correlation. The kinetic energy cutoff of 450 eV was adopted for the wave function expansion. Moreover, Brillouin zone integration on the grid with a $2 \times 2 \times 1$ k-grid mesh was performed for geometry optimization and calculation of density of states. A 13 Å vacuum layer thickness was applied to avoid virtual interaction. The $\text{MoS}_2/\text{Sb}_2\text{S}_3$ and $\text{MoS}_2/\text{Sb}_2\text{S}_3/\text{rGO}$ composites were assessed to reveal their structural and electronic properties. The corrected adsorption energy of Sb_2S_3 , $\text{MoS}_2/\text{Sb}_2\text{S}_3$ or $\text{MoS}_2/\text{Sb}_2\text{S}_3/\text{rGO}$ (ΔE_{ads}) was defined as.

$$\Delta E_{\text{ads}} = E_{\text{total}} - E_{\text{host}} - E_{\text{guest}} - E_{\text{Na}^+}$$

where E_{total} is the total energy of Sb_2S_3 , $\text{MoS}_2/\text{Sb}_2\text{S}_3$ or $\text{MoS}_2/\text{Sb}_2\text{S}_3/\text{rGO}$ surface adsorbed with Na^+ , while E_{host} and E_{guest} are the total energy of Sb_2S_3 , $\text{MoS}_2/\text{Sb}_2\text{S}_3$ or $\text{MoS}_2/\text{Sb}_2\text{S}_3/\text{rGO}$ and solo Na^+ , respectively.

3. Results and discussion

The synthesis process of $\text{MoS}_2/\text{Sb}_2\text{S}_3/\text{rGO}$ is shown in Fig. 1. At first, the nanosheet-like $\text{Sb}_2\text{MoO}_6/\text{rGO}$ precursor was synthesized by hydrothermal and freeze-drying processes. Subsequently, the $\text{Sb}_2\text{MoO}_6/\text{rGO}$ precursor was subjected to a high-temperature vulcanization process in N_2 atmosphere to obtain a porous sheet-like $\text{MoS}_2/\text{Sb}_2\text{S}_3/\text{rGO}$ heterostructure. The freeze-dried rGO nanosheets were transformed into

Fig. 1. Schematic illustration of the synthesis process of $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$.

porous 3D internet-like structures, which completely covered on the surface of the $\text{MoS}_2@\text{Sb}_2\text{S}_3$ composite. Therefore, the as-prepared $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ porous nanosheets is expected to have larger specific surface area, high electrical conductivity and fast ion transport channels.

The morphologies of $\text{Sb}_2\text{MoO}_6/\text{rGO}$, $\text{MoS}_2@\text{Sb}_2\text{S}_3$ and $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ were observed by SEM. As shown in Fig. S1, $\text{Sb}_2\text{MoO}_6/\text{rGO}$ exhibits nanosheet morphology, and the average size is $\sim 7 \mu\text{m}$. The surface is smooth, and the elemental mapping indicates the uniform distribution of O, Mo, Sb on rGO sheets. As shown in Fig. 2a, the size of the $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ nanosheets has not changed, and most of the nanosheets are embedded in the three-dimensional graphene network, forming a three-dimensional interconnected conductive framework structure. The high-magnification SEM image of $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ nanosheets is shown in Fig. 2b. It can also be seen that $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ nanosheets are wrapped by graphene networks. The inset shows that the nanosheets surface presents a porous and wrinkled structure. The origination of porous wrinkled structure is probably due to the MoS_2 nanosheets generated by reorganizing binary metal oxides into metal sulfides at the lattice level during high-temperature sulfidation. The porous wrinkled network facilitates sufficient wetting between the electrolyte and active material, which could greatly facilitate Na^+ intercalation and deintercalation, and improve the reversibility of the material. As shown in Fig. S2(a, b), the size of $\text{MoS}_2@\text{Sb}_2\text{S}_3$ composite without adding GO is slightly reduced with similar porous structure, showing a nano-block structure with a length of 3–4 μm . Fig. S3 shows the SEM image of pure graphene oxide, it can be seen that graphene presents a three-dimensional network structure. It facilitates the anchoring effect of the $\text{MoS}_2@\text{Sb}_2\text{S}_3$ heterojunction, which is beneficial to buffer the huge volume expansion of the $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ composite during the charge–discharge process.

From the TEM image in Fig. 2(c, d), it can be further observed that the $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ composite is composed of many ultrathin

nanosheets with a large number of holes on the surface, $\text{MoS}_2@\text{Sb}_2\text{S}_3$ nanosheets are all embedded in the three-dimensional interconnected rGO, presenting a three-dimensional conductive framework structure, and this greatly increases the specific surface area of the composite material and facilitates the penetration process of the electrolyte into the material. Fig. 2d is the HRTEM image of $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$. The lattice spacing of 0.615 nm corresponds to the (002) crystal plane of MoS_2 (JCPDS: 24-0513). The lattice spacing of 0.565 nm is assigned to the (200) crystal plane of Sb_2S_3 (JCPDS: 73-0393), and the clear boundary between them proves the successful construction of the $\text{MoS}_2@\text{Sb}_2\text{S}_3$ heterojunction. Fig. 2e is the element mapping of $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$, which verifies that Sb, Mo, and S elements are uniformly distributed in the composite. The elemental mapping of $\text{MoS}_2@\text{Sb}_2\text{S}_3$ are shown in Fig. S2c.

The elemental composition of the samples was accurately determined by XRD. In Fig. S4a, all the diffraction peaks of $\text{Sb}_2\text{MoO}_6/\text{rGO}$ correspond to the XRD card (JCPDS NO. 26-0107) of the triclinic structure Sb_2MoO_6 . Fig. 3a is the XRD pattern of $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ composite, there are three diffraction peaks at 14.3° , 33.4° , and 39.5° , which belong to the the (002), (101) and (103) crystal planes of MoS_2 (JCPDS: 24-0513), respectively. The diffraction peaks at 17.5° , 24.9° , 29.2° , and 32.3° correspond to the (201), (103), (211) and (212) characteristic surfaces of Sb_2S_3 (JCPDS: 73-0393), respectively. The XRD pattern of $\text{MoS}_2@\text{Sb}_2\text{S}_3$ was also analyzed in Fig. S4b, and all diffraction peaks detected correspond exactly to standard cards of MoS_2 (JCPDS: 24-0513) and Sb_2S_3 (JCPDS NO. 26-0107), which proves the successful synthesis of $\text{MoS}_2@\text{Sb}_2\text{S}_3$.

$\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ bonds and valence states were measured by XPS. The survey spectrum in Fig. 3b shows that $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ contains the elements Sb, Mo, S, and C. The high-resolution Sb 3d XPS spectrum of the $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ composite split into two spin–orbit doublet states in Fig. 3c. The peaks at 539.1 eV and 540 eV can be connected to the Sb 3d_{3/2} state, and the peaks at 529.6 and 530.4 eV can be ascribed

Fig. 2. (a) Low magnification SEM images of MoS₂@Sb₂S₃/rGO. (b) High magnification SEM images of MoS₂@Sb₂S₃/rGO, the inset is a partial enlarged view of MoS₂@Sb₂S₃/rGO nanosheets. (c, d) TEM image of MoS₂@Sb₂S₃/rGO. (e) HRTEM image of MoS₂@Sb₂S₃/rGO and the corresponding lattice spacing profile. (f) element mapping of MoS₂@Sb₂S₃/rGO.

with the Sb 3d_{5/2} state [37], the photoelectron peaks at MoS₂@Sb₂S₃/rGO at 531.6 eV and MoS₂@Sb₂S₃ at 533.1 eV both belong to O 1s, which may be caused by partial absorption of oxygen and water when the sample is exposed to air. Compared with the MoS₂@Sb₂S₃ material, each peak in the Sb 3d spectrum (Fig. 3c), Mo 3d spectrum (Fig. 3d) and S 2p spectrum (Fig. 3e) of MoS₂@Sb₂S₃/rGO composites shift to lower binding energies, this result confirms the electronic coupling effect between MoS₂@Sb₂S₃ and 3D interconnected rGO, in which electrons transfer rapidly. In Fig. 3d, the Mo 3d peaks of the MoS₂@Sb₂S₃/rGO composite appeared at 232.4 eV (Mo 3d_{3/2}) and 229.3 eV (Mo 5d_{3/2}), compared with the MoS₂@Sb₂S₃ spectra (232.7 eV and 229.6 eV), moving to lower binding energy, the characteristic peak intensities are also smaller, indicating that rGO masks the peak intensities of the MoS₂ and Sb₂S₃ components [38]. As shown in Fig. 3e, in the MoS₂@Sb₂S₃/rGO composite, the sulfur peaks at 162.2 eV and 163.4 eV were ascribed to the S 2p_{3/2} and S 2p_{1/2} orbitals of S 2p, respectively, proving that the sulfurization was successful. Fig. 3f is the high-resolution C 1s XPS spectrum of MoS₂@Sb₂S₃/rGO, two peaks at 284.8 eV and 286.3 eV in the C 1s spectra are closely correlated with the C—C=C and C—O bonds, respectively [39]. The total spectrum of MoS₂@Sb₂S₃ is also given in Fig. S6a, Supporting Information, and Mo, Sb, and S elements are detected. The high-resolution XPS spectra of Sb₂MoO₆/rGO are analyzed in detail in Fig. S6, Supporting Information.

Fig. 3g and Fig. S7 present the Raman spectra of MoS₂@Sb₂S₃/rGO and Sb₂MoO₆/rGO, respectively. Two strong peaks were observed around 1340 and 1580 cm⁻¹ for both composites, corresponding to D band and G band, respectively, confirming the existence of rGO. In Fig. 3g, the small characteristic peak at 100–300 cm⁻¹ belongs to Sb₂S₃, and the MoS₂ in-plane E_{2g}¹ and out-of-plane A_{1g} vibrations are represented by the two sharp peaks at 378 and 403 cm⁻¹, respectively, confirmed the successful formation of MoS₂@Sb₂S₃ heterojunction. In

Fig. S7, the two peaks at 716 and 812 cm⁻¹ are ascribed to Sb₂MoO₆. Fig. 3h shows the specific surface area of MoS₂@Sb₂S₃/rGO by measured BET method to be 33.1828 m² g⁻¹, which is larger than those of Sb₂MoO₆/rGO (30.0743 m² g⁻¹) and MoS₂@Sb₂S₃ (24.6340 m² g⁻¹), demonstrating that the introduction of 3D interconnected rGO increased the specific surface area, facilitated electrolyte penetration, and provided more reactive sites for Na⁺ intercalation. Fig. 3i and Fig. S8 are the pore size distribution diagrams of MoS₂@Sb₂S₃/rGO and MoS₂@Sb₂S₃, respectively, and the measured average pore sizes of MoS₂@Sb₂S₃/rGO and MoS₂@Sb₂S₃ are 8.1314 nm and 9.658 nm, respectively.

In order to explore the reduction–oxidation behavior of MoS₂@Sb₂S₃/rGO during sodium storage, we performed CV tests. In Fig. 4a, the first broad peak appears around 1.25 V during the first discharge, indicating that Na⁺ intercalate into the MoS₂ lattice [40]. A reduction peak appeared around 0.87 V and disappeared in subsequent scans, it was proved that the solid electrolyte interface (SEI) film was formed. The two reduction peaks at 0.68 V and 0.4 V correspond to the transformation of Sb₂S₃ components and the further alloying of Sb⁰ to form by-products, respectively [41]. The sharp peak at 0.01 V is attributed to the formation of Na_xMoS₂ [42]. The Na_xMoS₂ and Mo phases formed during the discharge process can both reduce the volume expansion when the Sb₂S₃ components are converted to Sb⁰ and Na₃Sb, thereby ensuring the structural stability of the MoS₂@Sb₂S₃/rGO composite [43]. During the first charge, the oxidation peaks at 0.75 V and 1.3 V are assigned to the reverse transformation of Na₃Sb and the formation of Sb⁰ components, respectively [44]. The broad peaks at 1.84 V and 2.34 V correspond to the process of Na⁺ extraction to form MoS₂ and Sb₂S₃ components [45]. In the subsequent second and third scans, the CV curves are highly overlapped, indicating that the composite has superb structural stability and high electrochemical reversibility. The CV curves of Sb₂MoO₆/rGO and MoS₂@Sb₂S₃ are shown in Fig. S9a, b,

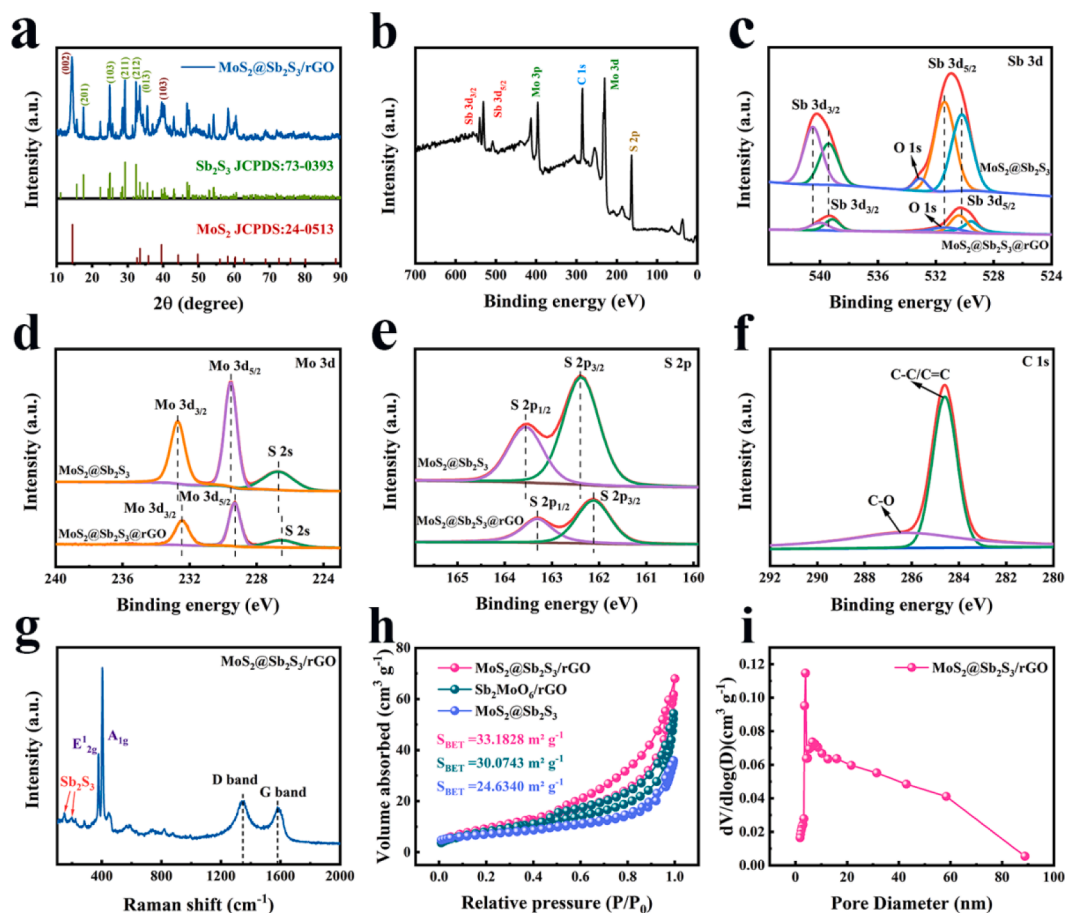

Fig. 3. (a) XRD patterns of MoS₂@Sb₂S₃/rGO. (b) High-resolution XPS Survey spectra of MoS₂@Sb₂S₃. (c-e) are High-resolution of Sb 3d, Mo 3d and S 2p XPS spectra of MoS₂@Sb₂S₃ and MoS₂@Sb₂S₃/rGO composite. (f) High-resolution C 1s XPS spectra of MoS₂@Sb₂S₃/rGO. (g) Raman spectra of MoS₂@Sb₂S₃/rGO. respectively. The electrochemical reactions of MoS₂@Sb₂S₃/rGO during sodium storage are as follows:

The GCD curves of MoS₂@Sb₂S₃/rGO at 0.1 A g⁻¹ for the first 5 cycles are shown in Fig. 4b. Generally, the significant capacity loss in the first cycle is attributed to the formation of SEI film. The first discharge capacity is 679 mAh g⁻¹ and the charging capacity is 547 mAh g⁻¹, corresponding to an initial coulombic efficiency of 80.6 %. The charge-discharge curves of the last four laps almost overlap, indicating that the battery capacity decays slowly. In contrast, as shown in Fig. S10a, the first charge-discharge capacity of Sb₂MoO₆/rGO is only 404 mAh g⁻¹ and 670 mAh g⁻¹, and the initial coulombic efficiency is 60 %. The charge-discharge curve of MoS₂@Sb₂S₃ is shown in Fig. S10b, the initial charge-discharge capacity is 488 mAh g⁻¹ and 601 mAh g⁻¹, respectively, and the initial coulomb efficiency is 81 %.

Fig. 4d compares the cycling performance of MoS₂@Sb₂S₃/rGO, Sb₂MoO₆/rGO, and MoS₂@Sb₂S₃. The MoS₂@Sb₂S₃/rGO exhibits a second discharge capacity of 618 mAh g⁻¹, which can provide a discharge capacity of 380.6 mAh g⁻¹ after 100 cycles at 0.1 A g⁻¹. In contrast, the capacity of Sb₂MoO₆/rGO and MoS₂@Sb₂S₃ electrode materials decreased significantly, the second discharge capacities are 470 mAh g⁻¹ and 502 mAh g⁻¹, respectively, and the specific capacities

after 100 cycles are 260 mAh g⁻¹ and 72 mAh g⁻¹, respectively. At the same time, it can be noticed that Sb₂MoO₆/rGO exhibits better cycle stability than MoS₂@Sb₂S₃, which is attributed to the coating of the 3D interconnected rGO network, buffering its volume expansion during the sodium deintercalation process.

The rate performances of MoS₂@Sb₂S₃/rGO, Sb₂MoO₆/rGO, and MoS₂@Sb₂S₃ are also investigated. As shown in Fig. 4(c, e), the electrode delivers discharge capacities of 678, 486.2, 413.2, 350.4, and 260.1 mAh g⁻¹ at 0.1, 0.2, 0.5, 1.0 and 5.0 A g⁻¹, respectively. The material's specific capacity was 588.5 mAh g⁻¹ when the current density was restored to 0.1 A g⁻¹, and the rate performance was basically recovered. In contrast, the Sb₂MoO₆/rGO and MoS₂@Sb₂S₃ anode materials in Fig. S11(a, b) exhibit poor rate performance. At 5 A g⁻¹, the discharge specific capacities are only 114 mAh g⁻¹ and 166 mAh g⁻¹, respectively. When recovered to 0.1 A g⁻¹, the discharge specific capacities are 377 mAh g⁻¹ and 325 mAh g⁻¹, respectively. Fig. 4f is a photo of a sodium-ion battery lighting an LED lamp based on MoS₂@Sb₂S₃/rGO electrode material.

The long-cycle performance of MoS₂@Sb₂S₃/rGO anode material at 5 A g⁻¹ was further tested. In Fig. 4g, the discharge capacity decreased sharply in the first 50 cycles, possibly due to the protective effect of the SEI film, which resulted in insufficient contact between the electrolyte and the active material, and difficulty in Na⁺ insertion/extraction. As the electrolyte slowly penetrated into the inside of the active material, the discharge capacity is stable after 200 cycles. The discharge capacity of 162 mAh g⁻¹ can still be maintained after 1100 cycles. As shown in the inset of Fig. 4g, Sb₂MoO₆/rGO without heterostructure and the MoS₂@Sb₂S₃ anode material without adding 3D interconnected rGO

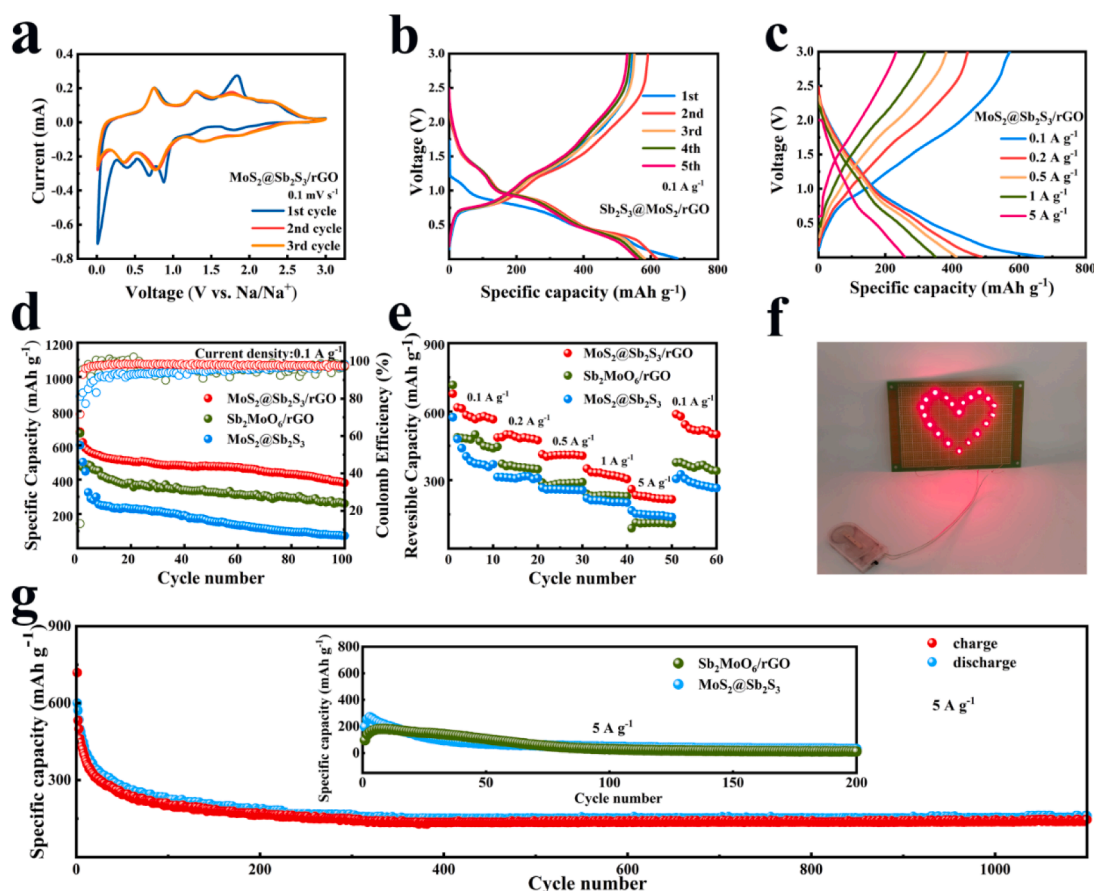

Fig. 4. (a) CV curves of $\text{MoS}_2@Sb_2S_3/rGO$ at a scan rate of 0.1 mV s^{-1} for the first three cycles. (b) GCD curves of $\text{MoS}_2@Sb_2S_3/rGO$ for the first five cycles at 0.1 A g^{-1} . (c) GCD curves of $\text{MoS}_2@Sb_2S_3/rGO$ at different current densities. (d) Cycling performance and coulombic efficiency of $\text{MoS}_2@Sb_2S_3/rGO$, Sb_2MoO_6/rGO and $\text{MoS}_2@Sb_2S_3$ at 0.1 A g^{-1} . (e) Rate capability of $\text{MoS}_2@Sb_2S_3/rGO$, Sb_2MoO_6/rGO and $\text{MoS}_2@Sb_2S_3$ at different current density. (f) Photo of lighting up LED lights. (g) Cycling stability of $\text{MoS}_2@Sb_2S_3/rGO$ anode at 5 A g^{-1} for 1100 cycles. The inset is the cycle performance diagram of $\text{MoS}_2@Sb_2S_3$ and Sb_2MoO_6/rGO at 5 A g^{-1} .

network will agglomerate and pulverize during the process of sodiation and desodiation, resulting in lower discharge capacity. After 200 cycles at 5 A g^{-1} , the discharge capacity almost drops to zero.

It can be thus concluded that $\text{MoS}_2@Sb_2S_3/rGO$ has high-rate performance and long cycle stability, which is mainly attributed to the formation of a unique heterostructure, and the interfacial energy of the heterointerface reaction and the electrode reaction's kinetics are enhanced. In the process of Na^+ intercalation and de-alloying, the formed interphase Na_xMoS_2 and Mo elements can effectively limit the volume expansion of the Sb_2S_3 component, thereby reducing the pulverization of electrode materials. In addition, the 3D interconnected rGO network also provides a abundant holes and active sites for the material, which facilitates the penetration of the electrolyte and improves the sodium storage performance of the composite [46,47].

The reaction kinetics of $\text{MoS}_2@Sb_2S_3/rGO$ was further analyzed by comparing the CV curves at various scan speeds. In Fig. 5a, with the increasing scan speeds, the redox peaks shifted in opposite directions with similar profiles, indicating that the charge storage process of $\text{MoS}_2@Sb_2S_3/rGO$ composites involves diffusion-controlled intercalation and surface capacitance processes [48]. Following is a description of the connection between scan rate (v) and peak current (i) [49]:

$$i = av^b \quad (5)$$

$$\log i = b \log v + \log a \quad (6)$$

Both a and b values can be adjusted. Diffusion control is dominant when b is equal to 0.5, and when the value of b is 1, it is dominated by the surface capacitive process [50]. In Fig. 5b, the b values of the five

peaks of the CV curve are all close to 1, indicating that the $\text{MoS}_2@Sb_2S_3/rGO$ composite is mainly dominated by the surface capacitance contribution, accompanied by a small part of the diffusion-controlled process. Additionally, at a certain scanning speed, the diffusion contribution and the surface capacitance contribution can be calculated by Equation (7) [51]:

$$i = k_1v + k_2v^{1/2} \quad (7)$$

k_1v and $k_2v^{1/2}$ represent the surface capacitance contribution and the diffusion contribution, respectively, and can be calculated from equation (7) at each scan speed. Fig. 5c demonstrates that the $\text{MoS}_2@Sb_2S_3/rGO$ composite has a capacitive control contribution of 94.1 % at 0.5 mV s^{-1} , which is greater than that of the Sb_2MoO_6/rGO (49.1 %, Fig. S12) and $\text{MoS}_2@Sb_2S_3$ (88.2 %, Fig. S13). According to Fig. 5d, the contribution of the $\text{MoS}_2@Sb_2S_3/rGO$ surface capacitance rises from 77.8 % to 97.3 % when the scan speed increases from 0.1 mV s^{-1} to 1 mV s^{-1} . The above results reveal that the sodium storage process of $\text{MoS}_2@Sb_2S_3/rGO$ composites is mainly dominated by the surface capacitance contribution, this result is mainly due to the formation of a porous sheet-like heterostructure with a unique wrinkle network, which accelerates the penetration of the electrolyte and enhances the Na^+ diffusion ability. At the same time, the close contact of p-type Sb_2S_3 and n-type MoS_2 makes the charge distribution around them non-uniform, which accelerates the transfer of Na^+ on the heterointerface.

The reaction kinetics were further analyzed by EIS test. As shown in Fig. 5e, the inset is the equivalent circuit diagram model, each Nyquist curve consists of a semicircle and a slope line. The Warburg impedance (Z_w) during Na^+ diffusion is shown by the oblique line, and the

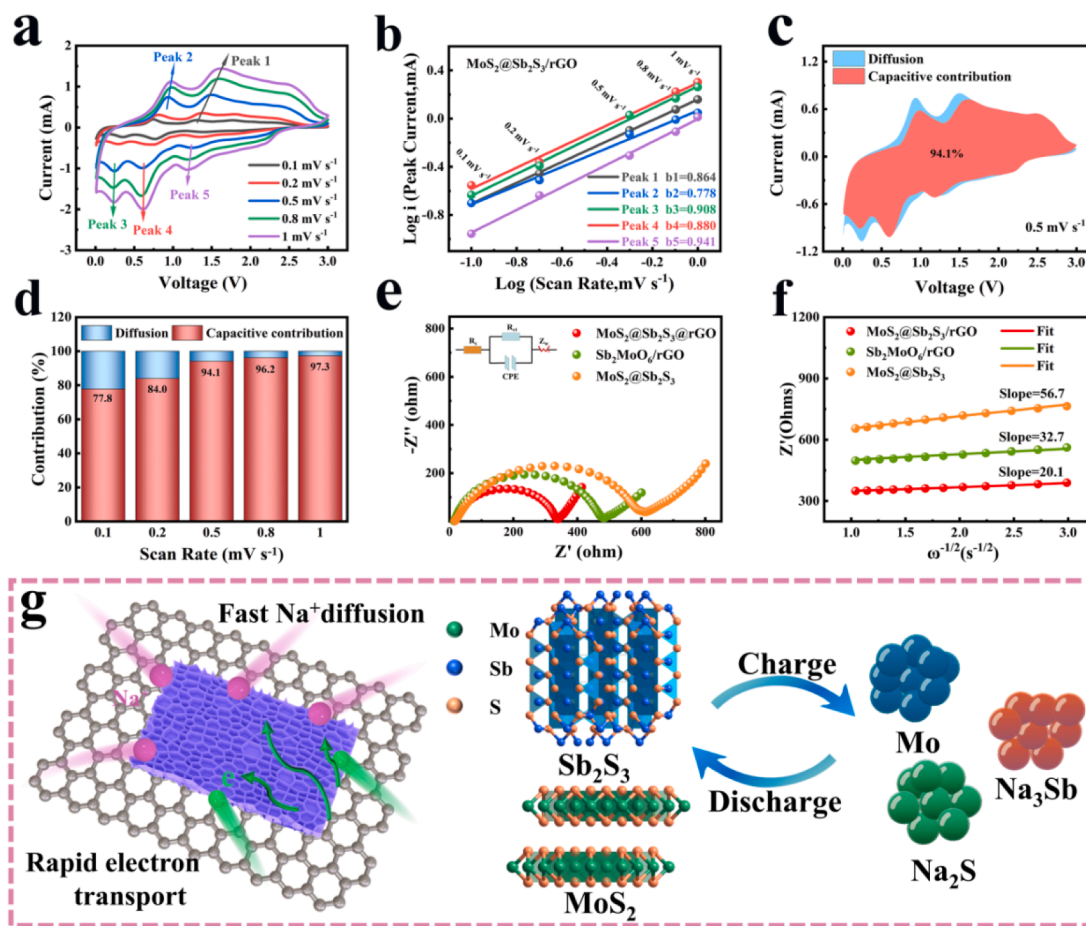

Fig. 5. (a) CV curves of MoS₂@Sb₂S₃/rGO at scan rates from 0.1 to 1.0 mV s⁻¹. (b) Fitting graph of log(i) and log(v) under each peak. (c) Capacitive contributed capacity ratio of MoS₂@Sb₂S₃/rGO at 0.5 mV s⁻¹. (d) Capacitive contribution ratio of MoS₂@Sb₂S₃/rGO at different scan rates. (e) EIS spectra of MoS₂@Sb₂S₃/rGO, Sb₂MoO₆/rGO, MoS₂@Sb₂S₃ and Sb₂MoO₆. (f) Relationships between Z' and ω^{-1/2} in the low frequency range of MoS₂@Sb₂S₃/rGO, Sb₂MoO₆/rGO and MoS₂@Sb₂S₃. (g) Schematic illustration of the sodium storage mechanism.

semicircle's diameter corresponds to the charge transfer impedance (R_{ct}). In Table S1, the charge transfer impedance (316 Ω) of MoS₂@Sb₂S₃/rGO is smaller than that of Sb₂MoO₆/rGO (457.5 Ω) and that of MoS₂@Sb₂S₃ (535.1 Ω), indicating that MoS₂@Sb₂S₃/rGO has excellent electrode kinetics. To further explore the Na⁺ transfer mechanism, the connection between Z' and ω^{-1/2} was plotted in Fig. 5f. The diffusion rate (D_{Na}) of Na⁺ can be calculated from Equation (8) [52]:

$$D_{Na} = R^2 T^2 / 2A^2 n^4 F^4 C^2 \sigma^2 \quad (8)$$

R, T, A, n, F, C, and σ indicate gas constant, absolute temperature, electrode surface area, transmitted electrons per unit mass, Faraday's constant, and Warburg factor, respectively. According to Table S1, the Na⁺ diffusion coefficient (D_{Na}) of MoS₂@Sb₂S₃/rGO superior to that of Sb₂MoO₆/rGO and MoS₂@Sb₂S₃, demonstrating that the 3D interconnected rGO network coated porous MoS₂@Sb₂S₃ heterostructure can accelerate Na⁺ transport rate, thereby enhancing the electrochemical reaction kinetics.

Fig. 5g reveals the reason for the significantly improved sodium storage performance of MoS₂@Sb₂S₃/rGO composites. Firstly, the construction of the heterostructure of porous MoS₂@Sb₂S₃ sheet not only shortens the Na⁺ diffusion distance, but also exposes more active sites. The different redox potentials of MoS₂ and Sb₂S₃ can also accommodate the huge volume changes during the process of sodiumization and desodiumization. Secondly, the two components MoS₂ and Sb₂S₃ will generate a phase boundary at the heterointerface, which will induce an internal electric field and accelerate the rapid transfer of Na⁺ and electrons, enhancing the electrochemical reaction kinetics. Thirdly, the

strong coupling between MoS₂ and Sb₂S₃ is beneficial to maintain the integrity of the Sb/Na₂S interface and alleviate the agglomeration of nanoparticles, and thus form a stable SEI film. Finally, the external 3D interconnected rGO network provides a conductive framework with abundant 3D channels, which accelerates the Na⁺ diffusion rate and facilitates the penetration of the electrolyte. Therefore, MoS₂@Sb₂S₃/rGO can exhibit high-rate capacity and ultra-long cycling life as an anode for SIBs.

In order to better explain the effect of heterostructure and graphene doping on the performance of composite materials, density functional theory (DFT) calculations were conducted [53–55]. Fig. 6(a–f) are the molecular model diagrams and three-dimensional differential charge density diagrams of the six structures of Sb₂S₃, Na-Sb₂S₃, MoS₂@Sb₂S₃, Na-MoS₂@Sb₂S₃, MoS₂@Sb₂S₃/rGO, and Na-MoS₂@Sb₂S₃/rGO, respectively, in which blue represents the increase of electron density, yellow represents the decrease of electron density. Fig. 6(g–i) are projected density of states (PDOS) diagrams of the six models. Comparing Fig. S14(a, d), it can be found that the surface electron orbital of Sb₂S₃ overlaps with the Na⁺ electron orbital, forming a strong adsorption. It can be seen in Fig. 6(g, j) that the energy maximum of PDOS orbital after Na⁺ adsorption rises from 25.07 eV to 27.63 eV, corresponding to the increase in the specific capacity of the anode electrode material after adsorbing Na⁺ during the charging process, that is, the rise in the system's overall electron density. Comparing Fig. S14(d–f), it can be found that after combining MoS₂ on Sb₂S₃, the ability to adsorb Na⁺ is weakened, which facilitates the release of Na⁺ from the anode electrode material during discharge. The introduction of graphene provides

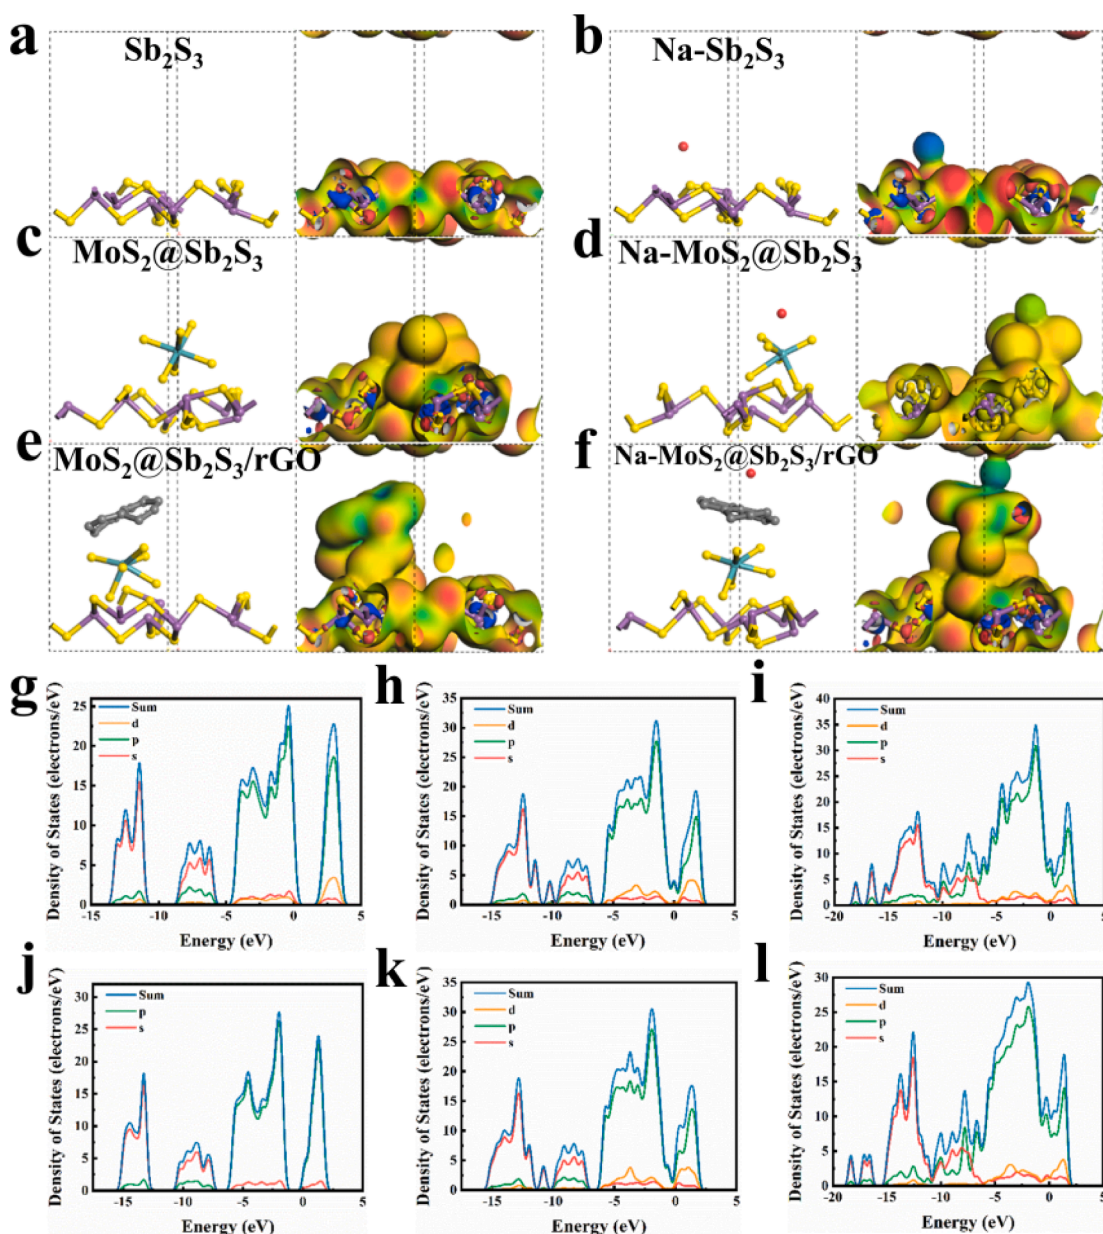

Fig. 6. Molecular models and 3D views of differential charge density for Sb_2S_3 (a), $\text{Na-Sb}_2\text{S}_3$ (b), $\text{MoS}_2@\text{Sb}_2\text{S}_3$ (c), $\text{Na-MoS}_2@\text{Sb}_2\text{S}_3$ (d), $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ (e), $\text{Na-MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ (f). Projected density of states (PDOS) for Sb_2S_3 (g), $\text{Na-Sb}_2\text{S}_3$ (j), $\text{MoS}_2@\text{Sb}_2\text{S}_3$ (h), $\text{Na-MoS}_2@\text{Sb}_2\text{S}_3$ (k), $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ (i), $\text{Na-MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ (l).

abundant electrons for the composite material, and the surrounding delocalized electron density increases, improving the conductivity of the anode material, which is consistent with the results in Fig. 5(e, f). The reason is that sp^2 and sp^3 in carbon materials are hybridized with a large number of loose electron clouds, which can effectively transport electrons. Comparing Fig. 6(g-i), it can be found that after Sb_2S_3 is compounded with MoS_2 and rGO, the bandgap at the top of the valence band and the bottom of the conduction band is filled, which increases the conductivity of the composite material.

In addition, the specific adsorption energy values for Na^+ were calculated. The adsorption energy of Sb_2S_3 to Na^+ is 10.34 eV, the adsorption energy of $\text{MoS}_2@\text{Sb}_2\text{S}_3$ to Na^+ is 3.03 eV, and the adsorption energy of $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ to Na^+ is 0.529 eV. The huge interaction force between pure Sb_2S_3 and Na causes Na^+ to be firmly embedded in the Sb_2S_3 lattice, and it is difficult to come out during discharge, resulting in low coulombic efficiency. After the introduction of MoS_2 and rGO on the basis of Sb_2S_3 , the adsorption capacity of Na^+ is

weakened in turn, which facilitates the adsorption and deintercalation of Na^+ , and improves the reaction reversibility and cycle stability of the composite material.

In Fig. S15(a, b), from the SEM images of $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ composite after 100 cycles at 0.1 A g^{-1} , the porous nanosheet structure was well maintained without significant pulverization, indicating the excellent structural stability of the nanocomposite. Table S2 compares the present results with previous reports. While different reports based on different measurement conditions, it can be concluded that present $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ composite as anode of SIBs achieved excellent performance specially in long-term cycle stability. At the same time, the $\text{MoS}_2@\text{Sb}_2\text{S}_3/\text{rGO}$ composites exhibit competitive coulomb efficiencies (99 %, Fig. 4 d) compared with Sb and Mo based materials in Table S2. Its excellent electrochemical performance benefits from the new design of the three-dimensional interconnected conductive skeleton structure, which greatly shortens the Na^+ diffusion path and improves the conductivity and structural stability of the electrode material. Furthermore,

the formation of a heterostructure between MoS₂ and Sb₂S₃ facilitates the electron transfer kinetics and enhances the electrochemical performance of the composite.

4. Conclusion

In summary, the porous MoS₂@Sb₂S₃/rGO composite is prepared by hydrothermal and high-temperature sulfidation method for anode material of SIBs. The heterogeneous interface between Sb₂S₃ and MoS₂ can induce internal electric field, which promotes Na⁺ pumping into the heterointerface and greatly reduces the activation barrier, thereby improving the whole material reaction kinetics. The MoS₂@Sb₂S₃ heterojunction is encapsulated in 3D interconnected rGO to form a conductive carbon framework. It provides certain mechanical toughness and higher specific surface area, buffering volume expansion during sodiumization and desodiumization, and providing 3D channels for the diffusion of Na⁺. The different redox potentials of MoS₂ and Sb₂S₃ are beneficial to reduce composite material volume expansion and increase the cycle stability of the electrode material, manifested in a second-cycle discharge specific capacity of 591.6 mAh g⁻¹ at 5 A g⁻¹ and 162.1 mAh g⁻¹ after 1100 cycles. DFT calculation shows that a large delocalized electron density is formed around MoS₂@Sb₂S₃/rGO composite, which optimizes the electronic structure, increases the material's conductivity, facilitates the adsorption energy of the composite for Na⁺, and promotes the reversibility of the electrochemical reaction.
